Session 2.3
Protecting our Oceans from Harmful Effects of Algal Bloom

Elvira Z. Sombrito
Philippine Nuclear Research Institute (retired)
Quezon City, Philippines
The HAB Problem

- A high cell concentration of phytoplankton, usually dominated by a particular algal species that may cause toxicity in seafood or fish kill.

The solution: IAEA provided equipment, expert services and training: extended to other countries experiencing HABs in S.America, Africa, Asia and Middle East.

1. Morbidity Cost
2. Loss in Income, local
3. Loss in Exports
4. Government Cost

Receptor Binding Assay—measures toxin in seafoods
Pb-210 for pollution and cyst history
Impacts

RBA is 40x more sensitive than mouse bioassay
1. It provides early warning to avoid illnesses
2. It can allow earlier lifting of shellfish ban
3. Avoid halo effects- local market and exports

Pb-210 dating in understanding HABS
1. Pollution history
2. HAB cyst history

70 M USD/year
The Way Forward

- Integration of RBA in the National Monitoring Program
- Development of RBA-based field assay
- Mapping of Bays- historical pollution through lead-210 dating
